

**NPSH**

**Net Positive Suction Head**

# 1. Calculation of NPSH available

## Net Positive Suction Head available

NPSHa is defined as the pressure energy that is available to the fluid at the Pump inlet over and above the vapor pressure value of the liquid being pumped at that temperature.

The liquid starts with some pressure (generally atmospheric) at the suction reservoir. This pressure energy is then converted into elevation potential energy (for suction lift condition) and suction pipe losses as the liquid reaches the pump inlet. Hence,

$$NPSH_A = h_{atm} + h_g - H_s - h_f - h_{vap}$$

Where,  $h_{atm}$  = Atmospheric pressure head (m)

$h_g$  = gauge pressure reading at suction vessel (m), for general case when liquid is pressurized at Reservoir

$H_s$  = Pump Centerline elevation from suction level (m)

$h_f$  = Friction losses in suction pipe (m)

$h_{vap}$  = vapor pressure head at pumping temperature (m)

**Note:** NPSHr is the min NPSH required by the pump for safe operation, and is a pump characteristic. While, NPSHa is the actual NPSH available and is a system characteristic. For design,  $NPSH_R > NPSH_A$

## CALCULATION OF AVAILABLE NPSH

Fig. 1: Determination of Net Positive Suction Head available

Now, let us consider two different cases of (a) Suction lift condition (b) Suction head condition to calculate NPSHa:

CASE 1 (LIFT)

Fig. 2: Two cases of suction

CASE 2 (HEAD)

Provided,

Pipe losses = 1.5 m

Specific gravity of liquid = 0.8

Vapor pressure = 0.45 kgf/cm<sup>2</sup> (at the pumping temperature of the liquid)

Now, we have to find out the value of NPSH<sub>a</sub> for the two cases below:

a) The suction lift = 3.0 m

b) The suction head = 4.0 m

**Note: The suction vessel is open**

### Description

Vapor pressure is 0.45 kgf/cm<sup>2</sup>

We know,

$$\text{Pressure (kg/cm}^2\text{)} = \frac{\text{head (m)} \times \text{specific gravity}}{10}$$

Using this we can calculate the atmospheric pressure head ( $h_{atm}$ ), vapor pressure head ( $h_{vap}$ ) etc.

$$h_{vap} = 5.6 \text{ m} \quad h_f = 1.5 \text{ m}$$

$h_{atm}$  (in terms of water) = 10.325 m water column.

$$h_{atm} \text{ (Equivalent column of the liquid being used)} = \frac{10.325}{\text{specific gravity}} = 12.9 \text{ m}$$

The vessel is open so it is at atmospheric pressure.

So,  $h_g = 0 \text{ m}$

$h_g$  is gauge pressure converted to head compared to atmospheric head (m).

### Case -1

We know, for the **suction lift condition**

$$\begin{aligned} NPSH_A &= h_{atm} + h_g - H_s - h_f - h_{vap} \\ &= (12.9 + 0 - 3 - 1.5 - 5.6) \text{ m} \end{aligned}$$

Putting the values in the equation, we get the value of  **$NPSH_A = 2.8 \text{ m}$**

### Case -2

We know, for the **suction head condition**

$$\begin{aligned} NPSH_A &= h_{atm} + h_g - H_s - h_f - h_{vap} \\ &= (12.9 + 0 + 4 - 1.5 - 5.6) \text{ m} \end{aligned}$$

Putting the values in the equation, we get  **$NPSH_A = 9.8 \text{ m}$**

## 2. Determination of minimum NPSHa & Pump Selection

An end suction pump has been designed for the following duty:

$$Q = 1800 \text{ m}^3/\text{hr}$$

$$H = 38 \text{ m}$$

$$\text{Impeller eye diameter } (D_e) = 278 \text{ mm}$$

$$\text{NPSHr at design duty} = 7.5 \text{ m}$$

$$\text{Speed} = 1480 \text{ rpm}$$

$$\text{Specific gravity} = 1$$

We have to calculate the **Suction Energy** and determine the  **$NPSH_A$**  to ensure **cavitation free safe operation**.

### Description

**Suction Energy:** Generally, the pump is kept at some level above the sump (suction reservoir). The liquid uses its own energy to reach the pump inlet (**Pressure Energy** → **Elevation Potential Energy**). Suction energy, as the name suggests, is a measure of the liquid's energy used for suction from reservoir to pump inlet. Higher the Suction Energy, higher is the energy used from liquid to bring it from the suction reservoir to pump inlet. Thus, a higher value of suction energy indicates a lower liquid pressure at inlet and a higher chance of cavitation and corresponding damage extent.

$$\text{Suction energy } (S.E) = D_e \times N \times N_{ss} \times \text{sp. gravity}$$

Where,  $D_e$  = Impeller eye dia. (inches)

$N$  = speed of the pump (rpm).

$N_{ss}$  = suction specific speed in US units.

**Suction Specific Speed:** It is the measure of Pump's suction capability. Defined as,

$$N_{ss} = \frac{N \times \sqrt{\left(\frac{Q}{eye}\right)}}{NPSH_R^{0.75}}$$

Here,  $(Q/eye)$  is the flow rate entering from each individual eye of the pump inlet.

$N_{ss}$  is the Suction Specific Speed.

$NPSH_R$  is the NPSH required by the pump for cavitation free operation.

$$N_{ss} = \frac{1480 \times \sqrt{1800}}{75} = 11928 \text{ US units}$$

$$S.E. = 10.94 \times 1480 \times 11928 \times 1 = 193 \times 10^6$$

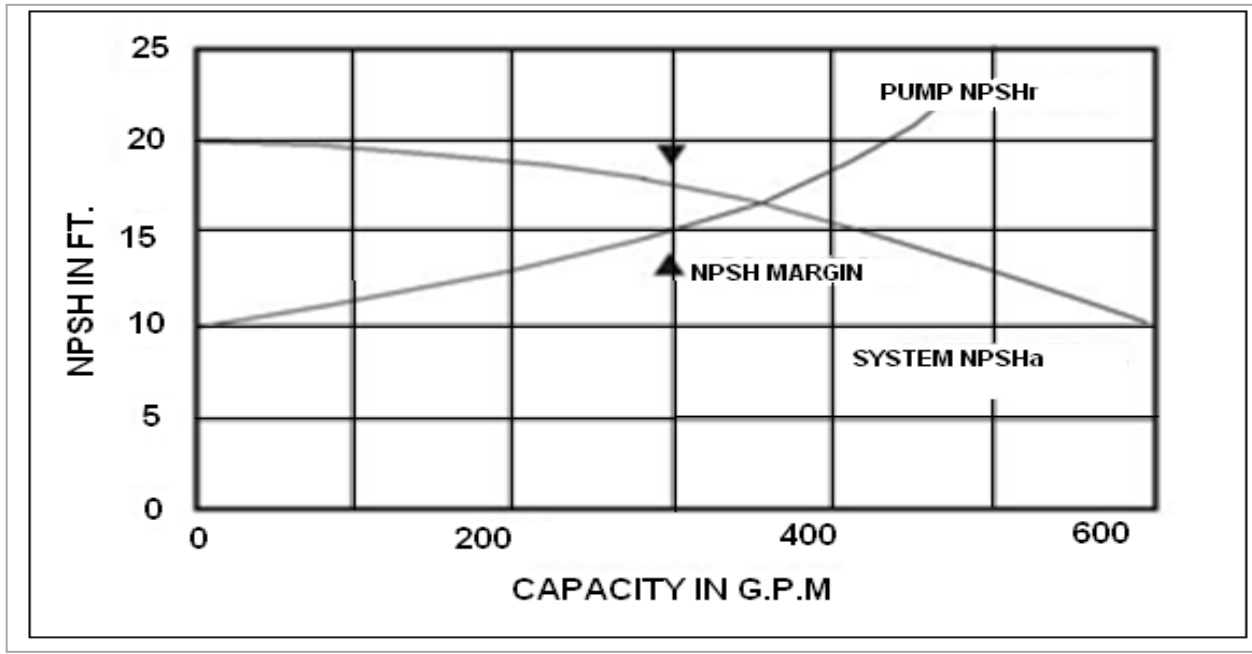

As discussed, the extent of cavitation damage depends on the value of suction energy. For design purpose, we assign different slabs for the magnitude of suction energy according to the type of pump, as shown below.

<b><u>PUMP TYPE</u></b>	<b><u>LOW S.E.</u></b>	<b><u>HIGH S.E.</u></b>	<b><u>VERY HIGH S.E.</u></b>
<b><u>2 VANE SEWAGE PUMP</u></b>	<b><u>&lt; 100 x 10<sup>6</sup></u></b>	<b><u>100 x 10<sup>6</sup> TO 150 x 10<sup>6</sup></u></b>	<b><u>&gt; 150 x 10<sup>6</sup></u></b>
<b><u>DOUBLE SUCTION PUMPS</u></b>	<b><u>&lt; 120 x 10<sup>6</sup></u></b>	<b><u>120 x 10<sup>6</sup> TO 180 x 10<sup>6</sup></u></b>	<b><u>&gt; 180 x 10<sup>6</sup></u></b>
<b><u>END SUCTION PUMPS</u></b>	<b><u>&lt; 160 x 10<sup>6</sup></u></b>	<b><u>160 x 10<sup>6</sup> TO 240 x 10<sup>6</sup></u></b>	<b><u>&gt; 240 x 10<sup>6</sup></u></b>
<b><u>VERTICAL TURBINE PUMPS</u></b>	<b><u>&lt; 200 x 10<sup>6</sup></u></b>	<b><u>200 x 10<sup>6</sup> TO 300 x 10<sup>6</sup></u></b>	<b><u>&gt; 300 x 10<sup>6</sup></u></b>
<b><u>INDUCERS</u></b>	<b><u>&lt; 320 x 10<sup>6</sup></u></b>	<b><u>320 x 10<sup>6</sup> TO 480 x 10<sup>6</sup></u></b>	<b><u>&gt; 480 x 10<sup>6</sup></u></b>

**Fig. 3: Suction Energy Level designation according to Pump Type**

For cavitation free operation, we must operate at a required  $NPSH_R$  value that is greater than the available system  $NPSH_A$ . We define a minimum NPSH margin for safe operation as shown below.

$$\text{Minimum NPSH margin} = \frac{NPSH_R}{NPSH_A}$$

**Fig. 4: NPSH<sub>R</sub> margin as function of operating point (region to the right of intersection is safe)**

Now, higher the suction energy level, higher is the extent of cavitation. Hence, we must assign a minimum NPSH<sub>R</sub> margin depending on the level of S.E. (higher margin for higher SE). According to **HIS**, the recommendation for safe operation is:

**HYDRAULIC INSTITUTE RECOMMENDS MINIMUM NPSH MARGIN FOR VARIOUS LEVELS OF SUCTION ENERGY**

<u>SUCTION ENERGY LEVEL</u>	<u>MINIMUM NPSH MARGIN (NPSH<sub>A</sub>/NPSH<sub>r</sub>)</u>
<u>LOW</u>	<u>1.1 TO 1.3</u>
<u>HIGH</u>	<u>1.3 TO 2</u>
<u>VERY HIGH</u>	<u>2 TO 2.5</u>

**Fig. 5: HIS Recommendation for minimum NPSH margin**

From the above data we can find out that for End Suction Pump, the duty point in consideration gives high S.E. value. Taking a conservative margin of 2 according to HIS recommendation:

The value of minimum NPSH<sub>A</sub> should be  $7.5 \times 2 = 15 \text{ m}$

**This minimum NPSH<sub>A</sub> is our criteria for proper pump selection.**
